Definition

Given

- Given
 - o a set V of locations,

- Given
 - o a set V of locations,
 - $\circ p \in \mathbb{Z}$, and

- Given
 - a set V of locations,
 - $\circ p \in \mathbb{Z}$, and
 - \circ distances d_{ii} from location $i \in V$ to $j \in V$

- Given
 - a set V of locations.
 - $\circ p \in \mathbb{Z}$, and
 - \circ distances d_{ii} from location $i \in V$ to $j \in V$
- · we want to
 - o open p locations of V, such that

- Given
 - a set V of locations,
 - $\circ p \in \mathbb{Z}$, and
 - distances d_{ij} from location $i \in V$ to $j \in V$
- we want to
 - open p locations of V, such that
 - the maximum distance of any location to its closest opened location is minimized.

The nesting property

Definition I

• given a set of locations *V*,

- given a set of locations *V*,
- time periods $\mathcal{H} = \{1, \dots, H\},\$

- given a set of locations V,
- time periods $\mathcal{H} = \{1, \dots, H\},\$
- integers $\mathcal{P} = \{p^1, \dots p^H\}$

- given a set of locations V,
- time periods $\mathcal{H} = \{1, \dots, H\},\$
- integers $\mathcal{P} = \{p^1, \dots p^H\}$
 - \circ where $p^h \leq p^{h+1}$ for $h = 1, \dots, H-1$ and
 - $\circ p^H \leq |\mathcal{J}|$

- given a set of locations V,
- time periods $\mathcal{H} = \{1, \dots, H\},\$
- integers $\mathcal{P} = \{p^1, \dots p^H\}$
 - \circ where $p^h \leq p^{h+1}$ for $h = 1, \dots, H-1$ and
 - $\circ p^H \leq |\mathcal{J}|$
- distances d_{ij} ≥ 0 between each i ∈ V and j ∈ V

Definition I

- given a set of locations V,
- time periods $\mathcal{H} = \{1, \dots, H\},\$
- integers $\mathcal{P} = \{p^1, \dots p^H\}$
 - \circ where $p^h \leq p^{h+1}$ for $h = 1, \dots, H-1$ and
 - $\circ p^H < |\mathcal{J}|$
- distances d_{ij} ≥ 0 between each i ∈ V and j ∈ V

Definition II

 a feasible solution to the nested *p*-center problem consists of a set J^h ⊆ V

Definition I

- given a set of locations V,
- time periods $\mathcal{H} = \{1, \dots, H\},\$
- integers $\mathcal{P} = \{p^1, \dots p^H\}$
 - \circ where $p^h \leq p^{h+1}$ for $h = 1, \dots, H-1$ and
 - $\circ p^H \leq |\mathcal{J}|$
- distances d_{ij} ≥ 0 between each i ∈ V and j ∈ V

- a feasible solution to the nested p-center problem consists of a set J^h ⊆ V
 - \circ with $|\mathcal{J}^h| = p^h$ for $h \in \mathcal{H}$,
 - o for which $\mathcal{J}^h \subseteq \mathcal{J}^{h+1}$ for $h = 1, \dots, H-1$ holds

Definition I

- given a set of locations V,
- time periods $\mathcal{H} = \{1, \dots, H\},\$
- integers $\mathcal{P} = \{p^1, \dots p^H\}$
 - where $p^h \le p^{h+1}$ for h = 1, ..., H-1and
 - $\circ p^H \leq |\mathcal{J}|$
- distances d_{ij} ≥ 0 between each i ∈ V and j ∈ V

- a feasible solution to the nested p-center problem consists of a set J^h ⊆ V
 - \circ with $|\mathcal{J}^h| = p^h$ for $h \in \mathcal{H}$,
 - for which $\mathcal{J}^h \subseteq \mathcal{J}^{h+1}$ for $h = 1, \dots, H-1$ holds
- the goal is to find a feasible solution which minimizes $\sum_{h=1}^{H} d_h(\mathcal{J}^h)$,
 - where $d_h(\mathcal{J}) = \max_{i \in \mathcal{I}} \min_{j \in \mathcal{J}} d_{ij}$ for $h \in \mathcal{H}$.

p-center problem vs nested p-center problem

The nested p-center problem: Potential applications

The pCP version of formulation (nPC3) has the best known linear programming (\mathcal{LP})-bounds for the pCP, while the pCP versions of (nPC1) and (nPC2) have equally but worse \mathcal{LP} -bounds.

Reducing set K in (nPC3)

Lemma 1

Let \underline{z}^h be a valid lower bound and \overline{z}^h be a valid upper bound on the decision variable z^h for $h \in \mathcal{H}$, then the distinct distance D_k can only be the optimal distance for z^h if $\underline{z}^h \leq D^k \leq \overline{z}^h$ holds.

Therfore let set $S_i^h \subseteq S_i$ for $h \in \mathcal{H}$, where S_i^h contains only the indices k where $\underline{z}^h \leq D^k \leq \overline{z}^h$ holds and constraint (4d) can be replaced with

$$u_k^h + \sum_{i:d_i < D_h} y_j^h \ge 1 \qquad \forall i \in \mathcal{I}, \forall h \in \mathcal{H}, \forall k \in \mathcal{S}_i^h \cup \{K\}$$
 (5)

Depending on the bounds \underline{z}^h and \overline{z}^h the sets S_i^h can be much smaller than S_i .

Strengthening constraints (nPC2)

Lemma 2

Let LB_h be a lower bound on the decision variable z_h of (nPC2) for every $i \in \mathcal{I}$, $j \in \mathcal{I}$ $\mathcal{J}, h \in \mathcal{H}$ then

$$z^h \ge max\{LB^h, d_{ij}\} - \sum_{j': d_{ij'} < d_{ij}} (max\{LB^h, d_{ij}\} - max\{LB^h, d_{ij'}\})y_{j'}^h$$
 (nL-OPT)

is a valid inequality for (nPC2), i.e., every feasible solution of (nPC2) fulfills (nL-OPT). Theorem is based on Lemma 5 in Gaar and Sinnl (2022).

A similar strengthening can be done for (??) in fromulation (nPC1).

Obtaining bounds I

Lemma 3

Let z'^{h*} be the optimal objective function value of pCP with $p = p^h$ for $h \in \mathcal{H} = \{1, 2, ..., H\}$ where $p^h > p^{h+1}$, then $UB = Hz'^{1*}$ is a valid upper bound on the optimal objective function value of n-pCP.

Then

$$\overline{z^h} = \frac{UB - \sum_{x=h+1}^{H} z'^{x*}}{h+1}$$

where $\overline{z^h}$ is a valid upper bound on the decision variable z^h of the n-pCP for $h \in \mathcal{H}$.

Obtaining bounds II

Lemma 4

Let z'^* be the optimal objective function value of pCP for a certain p'. Then z'^* is a valid lower bound \underline{z}^h on the decision variable z^h of n-pCP with $p^h = p'$.

Implementation and outline of the results

Implementation

- Implemented in C++ using the CPLEX API of CPLEX 20.1.0.0
- Formulation (nPC2) solved by branch-and-cut and seperation based on the customers
- Preprocessing for all formulations
 - solving the *p*CP for p^h , $h \in \mathcal{H}$ starting with h = H
 - $\circ p^h$ is a valid lower bound for the pCP with p^{h-1}
- Single core of an Intel Xeon X5570 machine
 - o 2.93 GHz
 - 48 GB RAM
 - Each run limited to 9 GB RAM and 3600 sec

Data

- data set PMED from "A note on solving large p-median problems" by Beasley (1985)
 - o set of 40 test instances
 - the sets contain between 100 and 900 nodes
 - o number of facilities to open initially ranging from 5 to 200

$$\mathcal{P} = \{p, p + 1, p + 2\}$$

Data

- data set PMED from "A note on solving large p-median problems" by Beasley (1985)
 - set of 40 test instances
 - the sets contain between 100 and 900 nodes
 - o number of facilities to open initially ranging from 5 to 200
 - $\circ \mathcal{P} = \{p, p + 1, p + 2\}$
- data set TSPLIB 2D-Euclidean distances from "TSPLIB—A Traveling Salesman Problem Library" by Reinelt (1991)
 - set of 80 test instances
 - the sets contain between 51 and 1002 nodes
 - o rounded to the nearest integer value
 - $\circ \mathcal{P} = \{4, 5, 6\}$

Preprocessing

Figure: Preprocessing

25

(nPC1)-results

(nPC2)-results

(nPC3)-results

Formulation comparison

Managerial insights

Figure: On a subset of instances: Only if the problem was solved to optimality

Conclusion

- (nPC3) had the best runtimes over all instances
- For optimality gap the results are rather mixed
- The (nPC2) outperforms the (nPC1)
- Maximal relative regret of the objective value of 15%
- Maximal relative regret of number of facilities above 140%
- min-max regret as objective function was also analysed and can be found later in the thesis
